I have been studying the water level in Texas. More directly the dead pool levels. A dead pool is a point where a water reservoir drops below a certain point that makes it unable to flow downstream. This can be important because it causes things such as people and hydro electric generators relying on this flow to be without the water. Another part of the set I was looking at was conservation pool elevation. This is the top of the normal operating level for a water reservoir. Its importance is similar to dead pool because if it drops it will cause many things that need the water to be without water.

The authors of the data I used were a group of people from the Texas Water Development Board (TWDB) Water Science and Conservation group and it was made possible by the support of management and staff at TWDB. This project is part of our ongoing efforts to synthesize and communicate water-related data to scientists, policy makers and the public.
